

Publishing Your Changes

How an edit travels from the workspace to your live website.

| The big picture

Making a change is only half the job — the change also has to be published before the public can see it. Here is the whole journey at a glance:

The key thing to remember: a change that only lives in the workspace is not live yet. It becomes live once it is saved (“pushed”) to GitHub, and the host (Render) automatically rebuilds and publishes the site.

| The three places involved

- **The workspace** — where you make the edit and preview how it looks before publishing.
- **GitHub** — the official storage that holds the real copy of the site. Nothing goes live until it arrives here.
- **Render** — the host that runs the live website and republishes automatically when GitHub receives a new change.

| A couple of words in plain language

- **Commit** — saving a snapshot of your changes with a short note describing them.
- **Push** — sending your saved changes up to GitHub. This is the step that starts the path to going live.

| How to publish your change

Make and preview your change first, and make sure it looks right. Then, in the workspace:

- 1 **Open the version-control panel** (the branching icon in the left tool strip).
- 2 **Review the list of changed files** so you know exactly what you are about to publish.
- 3 **Write a short message** describing the change, e.g. “Updated hero headline and button color.”
- 4 **Click Commit, then Push.** Your change is now on its way to GitHub.

- 5 **Wait a few minutes for Render to rebuild**, then open your live website to confirm the change is there and looks right.

You can also simply ask the assistant to “commit and push these changes” — just always review what it is about to publish first.

Before every publish — quick checklist

- The change is a visual / wording change (not data, logins, payments, permissions, or settings). If it touches those, stop and ask your developer.
- You previewed it and it looks right.
- Your commit message clearly says what changed.

If something looks wrong after publishing, don't worry — nothing is permanent. You can roll back to an earlier checkpoint in the workspace, and every past version is saved in GitHub, so your developer can restore the last good version quickly. When in doubt, pause and send them a short note of what changed.
